

The Consequences of Religious Strictness for Political Participation

Online Appendix

This online appendix reports several robustness checks and alternative specifications to models from the article. The results in every table reported in this document were computed using the `mice` library in R 3.0.0. Results are computed over 1196 observations from the first wave of the Portraits of American Life Study (Emerson and Sikkink, 2006), which is described in more detail in Emerson, Sikkink and James (2010). The appendix proceeds as follows:

Section 1 re-reports the results from the print article for the sake of comparison, reporting all four equations in the recursive system. The treatment variable in these original results capture the degree to which an individual’s church has imposed major costs on the individual’s life though strictness.

Section 2 reports the results when using several alternate measures of the treatment variable, again reporting all four equations in the recursive system for each alternate measure.

Subsection 2.1 uses an exogenous (rather than self-reported) measure of strictness using expert evaluations reported by Iannaccone (1994). Iannaccone took a survey of sixteen religious scholars, asking them to rate the degree to which eighteen Christian denominations required distinctive behavior of their members on a seven-point scale. He took the average of their evaluations as a measure of strictness for each denomination Iannaccone (1994, 1191). We classified each of the denominations in Iannaccone’s data into groups that correspond with religious identification categories in the 2006 survey and averaged the denominations’ distinctiveness scores within each category. A respondent in a given category received this average score as his or her value of religious strictness. Specifically, we have expert scores for Catholics and Mormons, who are identified exactly in the data. Protestants who identify as “mainline” received the average score among Lutheran (ELCA), Presbyterian, American Baptist, Quakers, Reformed and Methodist. “Liberal” Protestants received the average score among Unitarian, Disciples of Christ, Episcopalian and United Church of Christ. “Pentacostal” Protestants received the score for Assemblies of God. “Fundamentalist” Protestants received the score for Lutheran (MO Synod). “Evangelical” Protestants received the average score between Southern Baptist, Seventh Day Adventist and Nazarene.

Subsection 2.2 uses self-reported religious liberalism-conservatism on a seven-point scale (with higher values meaning more liberal).

Subsection 2.3 uses a simple indicator coded 1 if the respondent is a member of an evangelical church, and 0 otherwise.

Section 3 reports the results of a model of Protestants only ($N = 574$), with a categorical variable based on which religious tradition the respondent identifies with. In each model, “evangelical” is the reference group all others are compared to.

Section 4 reports the results—using the original individualized strictness scale—of whether the individual separately participated in each of the nine acts of political participation. These results are reported to evaluate whether the aggregated count measure of participation reported in the print article mischaracterizes the role religious strictness may have on specific acts of participation. For all of the robustness checks reported in this document, we conclude that the findings reported in the print article are fair and representative of the results that would be found under a variety of researcher assumptions.

1 Original Results Using Individualized Measure of Religious Strictness
